Received 25 March 2004

Abstract

We present a new Fornberg-like method for the numerical conformal mapping of multiply connected regions exterior to circles to multiply connected regions exterior to smooth curves. The method is based on new, symmetric conditions for analytic extension of functions given on circular boundaries. We also briefly discuss a similar method due to Wegmann and compare some computations with both methods. Some examples of regions which exhibit crowding of the circles are also presented.

Keywords: Numerical conformal mapping; Multiply connected regions; Crowding

1. Introduction

In this paper we present a new numerical method for conformally mapping unbounded multiply connected regions exterior to \( n \) nonoverlapping disks to unbounded regions exterior to \( n \) nonoverlapping Jordan curves (\( n \geq 2 \)). The method was derived and studied in [1] and is essentially a “symmetrized” version of the method in [7]. The new setup makes the derivation, analysis, and coding much more straightforward than [7], especially for regions of connectivity greater than 2. The method is similar to [28] and we include some numerical comparisons. In addition, we discuss some examples where the geometry of the target region causes the circles in the computational region to nearly touch—an example of the so-called crowding phenomenon for multiply connected regions.

The new method uses the same Newton-like approach as the methods [7,28]. Each Newton iteration computes updates to the current approximations of the boundary correspondences and centers and radii of the circles. We show below that the inner linear system of equations at each Newton step is a discretization of the identity plus a compact operator and so the conjugate gradient method can be applied efficiently. For Fornberg-like methods, in general, using discretization by \( N \)-point trigonometric interpolation and FFTs leads to computational costs of \( O(N \log N) \) for the simply and doubly

connected maps and \(O(N^2)\) for the multiply connected maps. The fact that the inner linear systems for Fornberg-like methods are second kind (identity plus compact) integral operators was first recognized by Widlund [31] and Wegmann [25] for the simply connected case [9], and by [6,8] for the ellipse and doubly connected case. This attractive feature is hereby carried over to the multiply connected case. In this sense, the current work represents the culmination of research by the second author and his colleagues and students (see [5–8]) to extend Fornberg’s original method [9] to increasingly complex geometries.

The interested reader is referred to [11,14,30] for introductions to the numerical methods for conformal mapping. Most methods for numerical conformal mapping compute the conformal moduli and the boundary correspondences between the canonical and target domains. Canonical domains whose boundaries are circles are popular alternatives, since the fast Fourier transform (FFT) can be applied. There are two approaches to deriving such methods. These two approaches have developed in parallel and use essentially the same linearization. One approach, due mainly to Wegmann, solves the inner linear systems for the Newton updates of the boundary correspondences and moduli as Riemann–Hilbert (RH) boundary value problems for the circular domains. The other approach, first proposed by Fornberg [9] for the simply connected case and extended by DeLillo et al., derives the inner linear systems from conditions on the Fourier (Laurent) coefficients which guarantee analytic extension of functions on the boundaries into the computational domain; see [2] for an overview. Both approaches have been developed for the following canonical domains: the unit disk [9,24,8], the annulus [8,18,26], the ellipse [5,6,27,15] and multiply connected circular domains [1,7,15,28,29].

Other methods for the multiply connected case have been developed. In [23], Wang has implemented the Koebe method [13,14] for the circle maps using both the exterior simply connected methods of Wegmann and of Fornberg [8] to successively map the exterior of each boundary component to the exterior of a disk. Prosnak has developed a linearly convergent projection method for this mapping problem; see [16,22,30]. The book [21] gives many applications of this method to problems in fluid dynamics. The reader can find more references for the multiply connected case in [7,28,30].

The remainder of this paper is organized as follows: we state the circle map problem in Section 2. In Section 3, we derive the analyticity conditions. After giving the linearization adopted in Section 4, we formulate the discrete problem as a linear system in Section 5. In Section 6, we provide an analysis of the inner linear system, showing that it is increasing in size. Wegmann’s method for the circle map is outlined in Section 7 and some numerical examples comparing both methods are given in Section 8. In Section 9, we give a brief discussion of the crowding for the circle map and present some illustrative examples and estimates.

### 2. The circle map problem

We are seeking a conformal map \(f\) from the complement, \(D\), of \(n\) closed nonintersecting disks, \(D_k\), onto a region \(\Omega\) which is exterior to \(n\) nonintersecting smooth Jordan curves, \(C_k\), \(1 \leq k \leq n\). Fig. 1 shows both the computational circle domain and the target domain. The following theorem, stated for the \(f^{-1}\) in [14], establishes the existence and uniqueness of the circle map under suitable normalization conditions.

**Theorem 2.1.** Let \(\Omega\) be a region of connectivity \(n \geq 2\) in the extended complex plane such that \(\infty \in \Omega\). Then there exists a unique circular region \(D\) of connectivity \(n\) and a unique one-to-one analytic function \(f\) in \(D\) satisfying

\[
f(z) = z + O(1/z) \quad \text{for } z \approx \infty, \tag{1}
\]

such that \(f(D) = \Omega\).

The boundaries of the circular disks \(D_k\) are the circles \(C_k\) with centers \(z_k\) and radii \(\rho_k\) and are parametrized by \(c_k(\theta) := z_k + \rho_k e^{i\theta}\). The boundary of \(D\) is thus \(C = C_1 + \cdots + C_n\). The boundary of \(\Omega\) is \(\Gamma = \Gamma_1 + \cdots + \Gamma_n\), where the boundaries \(\Gamma_k\) are parametrized by \(S\), e.g., arclength, \(\gamma_k : \gamma_k = \gamma_k(S)\). For smooth \(\gamma_k\), \(f\) extends smoothly to the boundary \(f(C_k) = \Gamma_k\). The values of \(f\) on \(C\) will determine \(f\) everywhere. The circle map problem is, thus, to find the boundary correspondences \(S = S_k(\theta)\) and the conformal moduli \(z_k\), \(\rho_k\) such that

\[
f(z_k + \rho_k e^{i\theta}) = \gamma_k(S_k(\theta)), \quad 1 \leq k \leq n, \tag{2}
\]
where $f$ is analytic and has the normalization $f(z) = z + O(1/z), z \approx \infty$. The map $f$ then has the form

$$f(z) = z + \sum_{k=1}^{n} \sum_{j=1}^\infty a_{k,-j} \left( \frac{\rho_k}{z - z_k} \right)^j,$$

where, for any integer $j$, $a_{k,j} := (1/2\pi) \int_0^{2\pi} f(z_k + \rho_k e^{i\theta}) e^{-ij\theta} d\theta$ are the Fourier coefficients of the restriction of $f$ to the boundary $C_k$.

3. Symmetrized analyticity conditions

We will follow closely the proof of Theorem 14.3b in [14] and Section 24 in [19] for establishing necessary and sufficient conditions for the analytic extension of a function in Lip($C$) to the exterior of a simply connected domain.

**Theorem 3.1.** A function $h \in$ Lip($C$), extends analytically to a function $g$ in $D \cup \{\infty\}$ with $g(\infty) = 0$ if and only if for any $z \in \overline{D}$

$$\frac{1}{2\pi i} \int_C \frac{h(\zeta)}{\zeta - z} d\zeta = 0. \quad (4)$$

**Proof.** We give a brief sketch of the proof. Define

$$g^+(\zeta) := \lim_{\substack{z \to \zeta \\
z \in \overline{D}}} g(z) \quad \text{and} \quad g^-(\zeta) := \lim_{\substack{z \to \zeta \\
z \in \overline{D}^\circ}} g(z).$$

($\Rightarrow$): If $g$ is analytic in $D \cup \{\infty\}$ ($g(\infty) = 0$) with $g^+(\zeta) = h(\zeta)$, then for $z \in \overline{D}^\circ$, the function $h(\zeta)/(\zeta - z)$ is analytic for $\zeta \in D$ and continuous for $\zeta \in \overline{C}$. Therefore, we have

$$\frac{1}{2\pi i} \int_C \frac{h(\zeta)}{\zeta - z} d\zeta = \frac{1}{2\pi i} \int_C \frac{g(\zeta)}{\zeta - z} d\zeta = 0.$$

($\Leftarrow$): Let

$$g(z) := \frac{1}{2\pi i} \int_C \frac{h(\zeta)}{\zeta - z} d\zeta, \quad z \notin C$$
and assume \( g(z) = 0 \) for \( z \in \overline{D} \). Then \( g^{-}(\zeta) = 0 \). By the Sokhotskiy formula \[14, \text{Theorem 14.1c}\] applied to the multiply connected domain \( D \); see e.g. \[19\], we have

\[
h(\zeta) = g^+(\zeta) - g^-(\zeta) = g^+(\zeta), \quad \zeta \in C.
\]

Therefore, \( h(\zeta) \) extends analytically to \( g(z) \), \( z \in D \cup \{\infty\} \). (Note that this definition of \( g(z) \) gives \( g(\infty) = 0 \).) \( \square \)

Now we are ready to state our main theorem which gives the necessary and sufficient conditions for analytic extension of the conformal map from the boundary into the domain in terms of the Fourier coefficients \( a_{k,j} \). The conditions are a simpler, symmetrized version of the conditions used in \[7\]. We will need the binomial series

\[
\frac{1}{(1 - \Delta)^j} = \sum_{j=0}^{\infty} B_{k,j} \Delta^j, \quad |\Delta| < 1,
\]

where the binomial coefficients \( B_{k,j} \) are given by

\[
B_{k,j} = \frac{k(k+1)\cdots(k+j-1)}{j!}, \quad k \geq 1, \quad j \geq 1, \quad B_{k,0} = 1.
\]

**Theorem 3.2.** Let \( D \) be the region exterior to the circles \( C_k : z_k + \rho_k e^{i\theta}, 1 \leq k \leq n \). Suppose \( f \in \text{Lip}(C) \) has the Fourier series representation

\[
f(z_k + \rho_k e^{i\theta}) = \sum_{j=-\infty}^{\infty} a_{k,j} e^{i\theta}, \quad 1 \leq k \leq n.
\]

Then \( f \) extends analytically into \( D \) with \( f(z) = z + \mathcal{O}(1/z) \) for \( z \approx \infty \) if and only if

(i) for all centers \( z_k \)

\[
\frac{1}{2\pi i} \int_{C} \frac{f(\zeta) - \zeta}{(\zeta - z_k)^j} d\zeta = 0, \quad j \geq 1;
\]

(ii) or equivalently,

\[
a_{k,j} - \left( \frac{\rho_k}{z_l - z_k} \right)^j \sum_{l \neq k} \sum_{v=0}^{\infty} B_{j+1,v} \left( \frac{\rho_l}{z_k - z_l} \right)^{v+1} a_{l,-v-1} = r_{k,j}, \quad j \geq 0,
\]

where \( r_{k,0} = z_k, r_{k,1} = \rho_k \) and \( r_{k,j} = 0 \) for \( j \geq 2 \).

**Proof.** To show the equivalence of condition (i), let \( z \in \overline{D} \). Then \( z \in D_k \) for some \( k \) and therefore \( |(z - z_k)/(\zeta - z_k)| < 1 \) for \( \zeta \in C \). From Theorem 3.1, a necessary and sufficient condition for analytic extension of \( h(\zeta) = f(\zeta) - \zeta \) is

\[
0 = \frac{1}{2\pi i} \int_{C} \frac{h(\zeta)}{\zeta - z} d\zeta = \frac{1}{2\pi i} \int_{C} \frac{h(\zeta)}{(\zeta - z_k)(1 - ((z - z_k)/(\zeta - z_k)))} d\zeta = \sum_{j=0}^{\infty} (z - z_k)^j \frac{1}{2\pi i} \int_{C} \frac{h(\zeta)}{(\zeta - z_k)^{j+1}} d\zeta.
\]

Since \( z \) was arbitrary in \( \overline{D} \), we must have

\[
\frac{1}{2\pi i} \int_{C} \frac{f(\zeta) - \zeta}{(\zeta - z_k)^{j+1}} d\zeta = 0, \quad j \geq 0.
\]
For the equivalence of condition (ii), we will apply condition (i) to \( g(z) = f(z) - z = O(1/z) \) for \( z \approx \infty \). Then for \( j \geq 0 \)

\[
0 = \frac{1}{2\pi i} \int_C \frac{g(\zeta)}{(\zeta - z_k)^{j+1}} \, d\zeta \\
= \frac{1}{2\pi i} \int_C \frac{f(\zeta)}{(\zeta - z_k)^{j+1}} \, d\zeta - \frac{1}{2\pi i} \int_C \frac{\zeta}{(\zeta - z_k)^{j+1}} \, d\zeta \\
= \frac{1}{2\pi i} \int_{C_k} \frac{f(\zeta) \, d\zeta}{(\zeta - z_k)^{j+1}} - \frac{1}{2\pi i} \int_{C_k} \frac{\zeta \, d\zeta}{(\zeta - z_k)^{j+1}} + \sum_{l \neq k} \frac{1}{2\pi i} \int_{C_l} \frac{f(\zeta) \, d\zeta}{(\zeta - z_k)^{j+1}},
\]

since

\[
\frac{1}{2\pi i} \int_{C_l} \frac{\zeta}{(\zeta - z_k)^{j+1}} \, d\zeta = 0 \quad \text{for } l \neq k, \ j \geq 0.
\]

Next note that

\[
\frac{1}{2\pi i} \int_{C_k} \frac{\zeta}{(\zeta - z_k)^j} \, d\zeta = z_k := y_{k,0}, \quad \frac{1}{2\pi i} \int_{C_k} \frac{\zeta}{(\zeta - z_k)^2} \, d\zeta = 1 := y_{k,1},
\]

and

\[
\frac{1}{2\pi i} \int_{C_k} \frac{\zeta}{(\zeta - z_k)^{j+1}} \, d\zeta = 0 := y_{k,j}, \quad j \geq 2.
\]

The above conditions can therefore be written as

\[
\frac{1}{2\pi i} \int_{C_k} \frac{f(\zeta) \, d\zeta}{(\zeta - z_k)^{j+1}} + \sum_{l \neq k} \frac{1}{2\pi i} \int_{C_l} \frac{f(\zeta)}{(\zeta - z_k)^{j+1}} \, d\zeta = y_{k,j}.
\]

Substituting \( \zeta = z_k + \rho_k e^{i\theta} \), \( d\zeta = i\rho_k e^{i\theta} \, d\theta \), with \( 0 \leq \theta \leq 2\pi \), we have

\[
\int_{C_k} \frac{f(\zeta) \, d\zeta}{(\zeta - z_k)^{j+1}} = \int_0^{2\pi} \frac{f(z_k + \rho_k e^{i\theta}) e^{i\theta} \, d\theta}{(\rho_k e^{i\theta} - z_k)^{j+1}} = \frac{2\pi i a_{k,j}}{\rho_k^j}.
\]

(7)

Also, for \( l \neq k \) and \( \zeta \in C_l \), we have \( |(\zeta - z_l)/(z_k - z_l)| < 1 \) and therefore,

\[
\int_{C_l} \frac{f(\zeta)}{(\zeta - z_k)^{j+1}} \, d\zeta = i\rho_l \int_0^{2\pi} \frac{f(z_l + \rho_l e^{i\theta}) e^{i\theta} \, d\theta}{(z_l + \rho_l e^{i\theta} - z_k)^{j+1}}
\]

\[
= i\rho_l \int_0^{2\pi} \frac{f(z_l + \rho_l e^{i\theta}) e^{i\theta} \, d\theta}{(z_l - z_k)^{j+1}(1 - (\rho_l e^{i\theta}/(z_k - z_l)))^{j+1}}
\]

\[
= \frac{i\rho_l}{(z_l - z_k)^{j+1}} \sum_{\nu=0}^{\infty} B_{j+1,\nu} \left( \frac{\rho_l}{z_k - z_l} \right)^\nu \int_0^{2\pi} f(z_l + \rho_l e^{i\theta}) e^{i(\nu+1)\theta} \, d\theta
\]

\[
= - \frac{2\pi i}{(z_l - z_k)^{j+1}} \sum_{\nu=0}^{\infty} B_{j+1,\nu} \left( \frac{\rho_l}{z_k - z_l} \right)^\nu a_{l,-\nu-1}.
\]

(8)

Combining the above, we obtain condition (ii). □
In Section 5, we will discretize condition (ii) using $N$-point trigonometric interpolation and express the discrete form of the conditions in matrix form $P\tilde{a} = r$, where the $\tilde{a}$ is an $nN \times 1$ vector with the discrete $a_{k,j}$'s as components. Combining these conditions with the linearizations in the next section will give us our inner linear system for the Newton updates of the boundary correspondences and centers and radii of the circles.

4. Linearization

Here we show how to linearize (2) with respect to $f$, $S_k(\theta)$, $z_k$, and $\rho_k$. We make an initial guess of $S_k(\theta)$ and correct it with the real, $2\pi$-periodic function $U_k(\theta)$. We use the following linearization for $U_k(\theta)$:

$$\gamma_k(S_k(\theta) + U_k(\theta)) \approx \xi_k(\theta) + \gamma'(S_k(\theta))U_k(\theta), \quad 1 \leq k \leq n,$$

where $\xi_k(\theta) := \gamma_k(S_k(\theta))$. The linearization for the corrections $\delta z_k$ and $\delta \rho_k$ to $z_k$ and $\rho_k$ is

$$(f + \delta f)(z_k + \delta z_k + (\rho_k + \delta \rho_k)e^{i\theta}) \approx f(z_k + \rho_k e^{i\theta}) + f'(z_k + \rho_k e^{i\theta})(\delta z_k + \delta \rho_k e^{i\theta}).$$

Equating the linear terms in (9) and (10) gives

$$(f + \delta f)(z_k + \rho_k e^{i\theta}) = \xi_k(\theta) + \gamma'(S_k(\theta))U_k(\theta) + \xi_k(\theta)(\delta \rho_k + \delta z_k e^{-i\theta}),$$

where

$$\zeta_k(\theta) := -f'(z_k + \rho_k e^{i\theta})e^{i\theta} = i\rho_k^{-1}\gamma'(S_k(\theta))S_k'(\theta).$$

These linearizations were first proposed in [18,7] and were rigorously justified in [28]. The conditions in Theorem 3.2 are applied to require that (11) are the boundary values of a function analytic in $D$. These conditions give linear equations for $U_k$, $\delta z_k$, $\delta \rho_k$. The discrete form of these equations is given next.

5. Discretization and matrix formulation

We will discretize our equations using $N$-point trigonometric interpolation. Let $\theta_j := (j - 1)2\pi/N$, $j = 1, 2, \ldots, N$. For $1 \leq k \leq n$ and $1 \leq j \leq N$, we define the $N$-vectors and $N \times N$ matrices

$$F := [w^{-(j-1)(\ell-1)}]_{1 \leq j, \ell \leq N} = \text{FFT matrix} \quad \text{where} \quad w = e^{-i2\pi/N},$$

$$E_k := \text{diag}(\gamma'(S_k(\theta_j))),$$

$$\tilde{S}_k := \frac{N}{2\pi} [S_k(\theta_{j+1}) - S_k(\theta_j)],$$

$$U_k := [U_k(\theta_j)],$$

$$\tilde{\gamma}_k := [\gamma_k(S_k(\theta_j))],$$

$$\tilde{\xi}_k := [i\rho_k^{-1}E_k\tilde{S}_k],$$

$$\tilde{f}_k := [f(z_k + \rho_k e^{i\theta})],$$

$$a_k := \frac{1}{N}Ff_k,$$

$$z := [e^{-i\theta}].$$

Let $N = 2M$. We now use $a_{k,j}$ to denote the discrete Fourier coefficients. By the $N$-periodicity of the discrete Fourier coefficients $a_{k,j} = a_{k,j-N}$, we note that

$$a_k = (a_{k,0}, a_{k,1}, \ldots, a_{k,N-1})^T = (a_{k,0}, a_{k,1}, \ldots, a_{k,M-1}, a_{k,-M}, \ldots, a_{k,-2}, a_{k,-1})^T.$$
We truncate the sums in the analyticity equations to \( M \) terms and we limit the number of equations to \( M \) by considering only \( 0 \leq j \leq M - 1 \). With the \( a_{k,j} \)'s as given above, the system of discrete equations is

\[
a_{k,j} - \sum_{l \neq k}^{M-1} \sum_{v=0}^{M-1} \left( \frac{\rho_k}{z_l - z_k} \right)^j B_{j+1,v} \left( \frac{\rho_l}{z_k - z_l} \right)^{v+1} a_{l,v-1} = r_{k,j},
\]

where, \( r_{k,0} = z_k, r_{k,1} = \rho_k \) and \( r_{k,j} = 0 \) for \( 2 \leq j \leq M - 1 \). Eq. (13) can be written in matrix form as follows:

\[
Pa = P_1a_1 + P_2a_2 + \cdots + P_na_n = r,
\]

where we write

\[
P = \begin{bmatrix} P_1 & P_2 & \cdots & P_n \end{bmatrix}
\]

and the \((nM \times 1)\) vector

\[
r := \begin{bmatrix} r_1 \\ r_2 \\ \vdots \\ r_n \end{bmatrix}
\]

with each \( r_k \) given by

\[
r_k = (z_k, \rho_k, 0, 0, \ldots, 0)^T \in C^{M \times 1}.
\]

Each \( P_k \) has the following block structure:

\[
P_k = \begin{bmatrix} 0 & P_{1,k} \\ \vdots & \vdots \\ 0 & P_{k-1,k} \\ I & 0 \\ 0 & P_{k+1,k} \\ \vdots & \vdots \\ 0 & P_{n,k} \end{bmatrix},
\]

where for \( l \neq k \), the submatrices \( P_{l,k} \) are all of order \( M \times M \) with entries \((\rho_l/(z_l - z_k))^j B_{j+1,v}(\rho_l/(z_k - z_l))^{v+1}\) properly arranged. (Details about the submatrices \( P_{l,k} \) can be found in [1].)

The linearization (11) can be written in matrix form

\[
Na_k = Ff_k = Fz_k + FE_kU_k + \delta \rho_k Fz_k + \delta \tilde{z}_k F(\tilde{z}^* z_k),
\]

where \(*\) denotes the Hadamard product.

For convenience, we present for the matrix formulation of our equations for connectivity \( n = 2 \). The generalization to arbitrary \( n \) is straightforward. Using block matrix notation, the analyticity conditions can be written:

\[
\begin{bmatrix} P_1 & P_2 \end{bmatrix} \begin{bmatrix} z_1 \\ z_2 \end{bmatrix} = \begin{bmatrix} \ell_1 \\ \ell_2 \end{bmatrix},
\]

Inserting the linearization conditions into (15) we obtain:

\[
P_1(FE_1U_1 + \delta \rho_1 Fz_1 + F(\tilde{z}^* z_1))(\text{Re} \, \delta \tilde{z}_1 + i \text{Im} \, \delta \tilde{z}_1) \\
\quad + P_2(FE_2U_2 + \delta \rho_2 Fz_2 + F(\tilde{z}^* z_2))(\text{Re} \, \delta \tilde{z}_2 + i \text{Im} \, \delta \tilde{z}_2) = g,
\]

where

\[
g := -[P_1 \quad P_2] \begin{bmatrix} Fz_1 \\ Fz_2 \end{bmatrix} + \begin{bmatrix} \ell_1 \\ \ell_2 \end{bmatrix}.
\]

If we define the \( M \)-vectors

\[
w_k = P_k Fz_k, \quad w_{\tilde{z}_k} = P_k F(\tilde{z}^* z_k), \quad k = 1, 2,
\]
the matrices

\[ P = [P_1 \ P_2], \quad W = [w_1 \ w_2 \ w_1 z_1 \ w_2 z_1 \ w_1 z_2 \ w_2 z_2] \]

as well as the \((2N + 6) \times 1\) vector of unknowns

\[ U = \begin{bmatrix} U_1 \\ U_2 \\ \delta \rho_1 \\ \delta \rho_2 \\ \text{Re} \ z_1 \\ \text{Im} \ z_1 \\ \text{Re} \ z_2 \\ \text{Im} \ z_2 \end{bmatrix} \]

then our system takes the form

\[
DU := \begin{bmatrix} P & W \end{bmatrix} \begin{bmatrix} F & 0 \\ 0 & E_1 \\ 0 & 0 \\ 0 & E_2 \\ 0 & 0 \end{bmatrix} U = g. \tag{18}
\]

Taking the “normal” equations and using the fact that \( U \) is real gives us

\[
\frac{2}{N} \text{Re}(D^H D)U = \frac{2}{N} \text{Re}(D^H g), \tag{19}
\]

which we write as

\[
AU = b,
\]

where \( A := (2/N) \text{Re}(D^H D) \) and \( b = (2/N) \text{Re}(D^H g) \). Notice that \( A \) is symmetric and positive (semi)definite. We will use the conjugate gradient method to solve this system for updating the boundary correspondences and the conformal moduli. The Newton update for \( k \)th component, at the \( i \)th Newton step is

\[
S_k^{(i+1)}(\theta) = S_k^{(i)}(\theta) + U_k^{(i)}(\theta),
\]

\[
\rho_k^{(i+1)} = \rho_k^{(i)} + \delta \rho_k^{(i)},
\]

\[
z_k^{(i+1)} = z_k^{(i)} + \delta z_k^{(i)}. \tag{20}
\]

We now summarize the main parts of the algorithm:

- **Input** the boundary of each component.
- If the boundary is not given by an analytic formula, fit each component with a periodic spline of period \( Tl_k \) parametrized by (chordal) arclength \( S \), as in [7]. This step produces the coefficients of the spline.
- **Initialize** the boundary correspondence by

\[
S_k^{(0)}(\theta_j) = (j - 1)Tl_k/N.
\]

- Initialize \( \rho_k \) and \( z_k \). The user can do this either by guess or by using a subroutine that finds the optimal values for \( r_k \) and \( z_k \) such that the circle best fits the curve of component \( k \).
- Set the maximum number of iterations (NWT) for the Newton process and for the conjugate gradient (CG) method.
- **Start** the Newton iteration. For \( 1 \leq i \leq \text{NWT} \), where \( i \) denotes the iteration number:

1. Use the boundary representation to interpolate the boundary at \( N \) points;
2. Form \( S_k, E_k, \hat{S}_k, \hat{S}_k, f_k, \hat{a}_k, \hat{b}_k, W \);
3. Form the nonzero blocks of the matrix \( P \);
4. Solve \( AU = b \) by the conjugate gradient method (multiplication by \( A \) can be done efficiently by successively applying each factor);
5. Update (20) at the mesh points \( \theta = \theta_j \).
6. Analysis of the inner linear system

In this section, we will analyze the matrix \( A \) and show that the eigenvalues are well-grouped around 1, except for a few outliers. We will assume that \( S \) is arclength, so that \( \gamma_k'(S) = e^{i\beta_k(S)} \), where \( \beta_k \) is the argument of the unit tangent. Again, we will only consider the case \( n = 2 \). Extension to general \( n \) is straightforward. We have

\[
A = \frac{2}{N} \text{Re}(D^HD) = \begin{bmatrix} A_{11} & A_{12} & X_1 \\
A_{21} & A_{22} & X_2 \\
X_1^T & X_2^T & W^HW \end{bmatrix},
\]

where \( A_{ij} := \frac{2}{N} \text{Re}(E_i^H F^H P_i P_j F E_j) \) and \( X_i := \frac{2}{N} \text{Re}(E_i^H F^H P_i^j W) \). To explain the overall distribution of the eigenvalues of \( A \), it is sufficient to study those of the leading principal submatrix

\[
\hat{A} = \begin{bmatrix} A_{11} & A_{12} \\
A_{21} & A_{22} \end{bmatrix}.
\]

By standard theorems in matrix theory, the eigenvalues of \( A \) and \( \hat{A} \) will interlace. Recall that

\[
[P_1 \quad P_2] = \begin{bmatrix} I & 0 & 0 & P_{1,2} \\
0 & P_{2,1} & I & 0 \end{bmatrix}.
\]

Therefore,

\[
\begin{bmatrix} P_{1}^H & P_{2}^H \end{bmatrix} [P_1 \quad P_2] = \begin{bmatrix} P_{1}^H P_{1} & P_{1}^H P_{2} \\
0 & P_{2,1}^H \end{bmatrix} = \begin{bmatrix} I & 0 & 0 & P_{1,2} \\
0 & P_{2,1}^H & I & 0 \end{bmatrix}.
\]

We can decompose \( P_{1}^H P_{1} \)

\[
P_{1}^H P_{1} = \begin{bmatrix} I & 0 & 0 & P_{1,2} \\
0 & P_{2,1}^H & I & 0 \end{bmatrix} = P_{1,2} + A_2,
\]

where

\[
A_2 = \begin{bmatrix} 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \end{bmatrix}
\quad \text{and} \quad
I_+ = \begin{bmatrix} I & 0 \\
0 & 0 \end{bmatrix}.
\]

Next note that \( A_{11} = \frac{2}{N} \text{Re}(E_1^H F^H P_1 P_1 F E_1) \) can be decomposed into two parts:

\[
A_{11} = \frac{2}{N} \text{Re}(E_1^H F^H I_+ F E_1) + \frac{2}{N} \text{Re}(E_1^H F^H A_2 F E_1) = A_{11}^{(1)} + A_{11}^{(2)}.
\]

The matrix \( A_{11}^{(2)} := \frac{2}{N} \text{Re}(E_1^H F^H A_2 F E_1) \) and the remaining matrices, \( A_{12} \) and \( A_{21} \), are discretizations of compact operators, since they are the product of bounded operators and integral operators with continuous kernels. The matrix \( A_{11}^{(1)} := \frac{2}{N} \text{Re}(E_1^H F^H I_+ F E_1) \) is the discretization of the \( I + R \) where \( I \) is the identity and \( R \) is a compact operator as shown next. Following paper [8], one can see that \( A_{11}^{(1)} \) is the discretization of

\[
\text{Re}(e^{-i\beta_1(I + iK + J)e^{i\beta_1}}) = I + R,
\]

where \( R = \text{Re}(e^{-i\beta_1(I + iK + J)e^{i\beta_1}}) \). Here \( K \) is the conjugation operator for the disk and \( Jh = (1/2\pi) \int_0^{2\pi} h(\theta) \sin(\theta) \sin(\phi) \) for each function \( h \) in \( L_2(0, 2\pi) \), the operator \( R \) can be written as a Fredholm integral operator

\[
R\phi(\theta) = \frac{1}{2\pi} \int_0^{2\pi} h(\phi) \sin((\theta - \phi)/2) - (\beta_1(\phi) - \beta_1(\theta))) \sin((\theta - \phi)/2) \, d\phi.
\]

For \( \gamma \) sufficiently smooth, the operator \( R \) is a symmetric compact operator on \( L_2 \); see [25, Section 4]. \( A_{22} \) can clearly be analyzed in the same way. As a consequence, the eigenvalues cluster around 1. This feature carries over to the block matrix \( \hat{A} \).
We present two plots showing the grouping of eigenvalues around 1 for two different geometries with \( N = 32 \). The first is Fig. 2 corresponding to a domain bounded by circles, so that \( f \) is the identity. We see a strong grouping around 1. Fig. 3 shows the grouping of the eigenvalues for a noncircular target domain bounded by cubic splines. The large outlying eigenvalues are associated with the \( W \) blocks.

7. Wegmann’s method

In this section we briefly describe another method for conformal mapping of multiply connected regions using Wegmann’s approach using RH problems (see [28,29]). In common with the Fornberg-like method, this method solves the circle map problem, i.e., finding the centers \( z_k \) and radii \( \rho_k (1 \leq k \leq n) \) and boundary correspondences \( S_k(\theta) \) such that

\[
 f(z_k + \rho_k e^{-i\theta}) := \gamma_k(S_k(\theta)), \quad 1 \leq k \leq n.
\]
The RH problems (24) and (25) can be solved by the method of successive conjugation (see [28–30]) using the FFT [25]. We start with the form of the map, which is called here \( \Psi \). (Note that, following [28], the parametrization is reversed.)

Using the linearization \( f, f' \), where \( h_k(z) = \exp \gamma_k(S_k(\theta)) + \gamma_k'(S_k(\theta)) U_k \),

\[
f(z_k + \rho_k e^{-i\theta}) + \delta f(z_k + \rho_k e^{-i\theta}) + f'(z_k + \rho_k e^{-i\theta}) (\delta z_k + \delta \rho_k e^{-i\theta}) = \gamma_k(S_k(\theta)) + \gamma_k'(S_k(\theta)) U_k,
\]

where \( \gamma_k(S_k(\theta)) = r_k(S_k(\theta)) e^{i\beta_k(S_k(\theta))} \).

At each Newton iteration, Wegmann’s method [24] requires the solution of two RH problems (24) and (25). \( f, \delta f, f', \) and \( \Psi \) are connected by \( f' = \exp(\Psi) \) and \( \Psi = (f + \delta f) / \exp(\Psi) \).

The algorithm for Wegmann’s method is as follows:

1. Given initial guesses \( S_k^{(0)}, z_k^{(0)}, \rho_k^{(0)} \) for the boundary correspondences, centers and radii.
2. For each Newton iteration \( i = 0, 1, 2, \ldots \)
   1. Compute \( v_k(\theta) = \beta_k(S_k(\theta)) + \theta + \pi/2 \).
   2. Solve the RH problem
      \[
      \text{Re}(iY + i\lambda_k) = -v_k.
      \] (24)
   3. Calculate \( F_k = \exp(-u_k - i\beta_k - i\lambda_k) \gamma_k \).
   4. Solve the RH problem
      \[
      \text{Re}(e^{i\theta} \Psi(z_k + \rho_k e^{-i\theta}) + a_k e^{i\theta} + \alpha_k) = \text{Im} F_k.
      \] (25)
   for analytic \( \Psi(z) = z + O(1/z) \) at \( \infty \).
   5. Compute the updates
      \[
      U_k(\theta) = -\frac{e^{u_k}}{r_k} (g_k + \text{Re} F_k),
      \]
      \[
      \delta z_k = a_k - \text{res}_\infty Y,
      \]
      \[
      \delta \rho_k = \alpha_k
      \]
      where \( \text{res}_\infty Y \) is the residue of \( Y \) at \( \infty \).
   6. Smooth \( U_k \): for the interpolating trigonometric polynomial
      \[
      U_k = \sum_{j=-N/2+1}^{N/2-1} \hat{a}_j e^{ij\theta} + \hat{a}_{N/2} \cos(N\theta/2),
      \]
      set \( \hat{a}_j = 0 \) for \( |j| \geq N/4 + 1 \).
   7. Update the boundary correspondences, centers, and radii by
      \[
      S_k^{i+1} = S_k^i + U_k,
      \]
      \[
      z_k^{i+1} = z_k^i + \delta z_k,
      \]
      \[
      \rho_k^{i+1} = \rho_k^i + \delta \rho_k.
      \]

The RH problems (24) and (25) can be solved by the method of successive conjugation (see [28–30]) using the FFT [25]. We start with the form of the map, which is called here \( \Psi \)

\[
\Psi(z) = \sum_{k=1}^{n} h_k(z) = \sum_{k=1}^{n} \sum_{m=1}^{\infty} b_{k,m} (z - z_k)^{-m},
\] (26)

where \( h_k(z) := \sum_{m=1}^{\infty} b_{k,m} (z - z_k)^{-m} \) is analytic in the exterior of \( D_k \).

We describe briefly the method of successive conjugation as applied to our problem. Let \( l \) be a nonnegative integer and \( \psi_k \) be real functions. The general form of the RH problem is to solve

\[
\text{Re}(e^{il\theta} \Psi(z_k + \rho_k e^{-i\theta}) + a_{k,1} e^{il\theta} + \cdots + a_{k,1} e^{il\theta} + a_{k,0}) = \psi_k, \quad 1 \leq k \leq n
\] (27)
for an analytic function $\Psi$ in $D$ with $\Psi(\infty) = 0$, real numbers $a_{k,0}$ and complex numbers $a_{k,1}, \ldots, a_{k,l}$. To solve the problem iteratively, given initial guesses $h_k^{(0)} = 0$, we can use a Gauss–Seidel-like method for Eq. (27)

$$\text{Re}(e^{it} h_k^{(k+1)}(z_k + \rho_k e^{-i\theta}) + a_{k,j} e^{it} + \cdots + a_{k,l} e^{it} + a_{k,0})$$

$$= \psi_k - \text{Re} \left( \sum_{\nu < k} e^{it} h_{\nu}^{(k+1)}(z_k + \rho_\nu e^{-i\theta}) \right) - \text{Re} \left( \sum_{\nu > k} e^{it} h_{\nu}^{(k)}(z_k + \rho_\nu e^{-i\theta}) \right)$$

$$= \sum_{m=-\infty}^{\infty} A_{k,m} e^{i\nu t},$$

where $\sum_{m=-\infty}^{\infty} A_{k,m} e^{i\nu t}$ is the Fourier series expansion of the RHS. It follows that

$$a_{k,0} = A_{k,0}, \quad a_{k,j} = 2A_{k,j}, \quad j = 1, \ldots, l, \quad (28)$$

$$b_{k,m} = 2\rho_k^m A_{k,m+l} \quad \text{for } m = 1, 2, \ldots. \quad (29)$$

The evaluation of $\Psi$ is of primary importance since, if it is not carefully arranged, it can lead to a very slow computation. Below, we show how to evaluate $\Psi$ in (26). The matrices $P_{k,l}$ arise naturally in this evaluation.

Using (29), we have

$$h_v(z) = 2 \sum_{m=1}^{\infty} \rho_v^m A_{v,m+l}(z - z_v)^{-m}.$$  

For $v = k$,

$$h_k(z_k + \rho_k e^{-i\theta}) = \sum_{m=1}^{\infty} 2A_{k,m+l} e^{i\nu t}$$

which can be computed efficiently by the FFT.

For $v \neq k$,

$$h_v(z_k + \rho_k e^{-i\theta}) = 2 \sum_{m=1}^{\infty} \rho_v^m A_{v,m+l}(z_k + \rho_k e^{-i\theta} - z_v)^{-m}$$

$$= 2 \sum_{m=1}^{\infty} \sum_{j=0}^{\infty} \left( \frac{\rho_v}{z_k - z_v} \right)^m \left( \frac{\rho_k}{z_v - z_k} \right)^j A_{v,m+l} B_{m,j} e^{-ij\theta}$$

$$= \sum_{j=0}^{\infty} \left[ \left( \frac{\rho_k}{z_v - z_k} \right)^j \sum_{m=0}^{\infty} B_{j+1,m} \left( \frac{\rho_v}{z_k - z_v} \right)^{m+1} (2A_{v,m+l+1}) \right] e^{-ij\theta}$$

$$:= \sum_{j=0}^{\infty} a_{v,k}^j e^{-ij\theta} \quad (30)$$

Numerically, we truncate the above equation to $M$ (here $M := (N/2) - l - 1$) terms to get

$$a_{j,v}^k = \left( \frac{\rho_k}{z_v - z_k} \right)^j \sum_{m=0}^{M-1} B_{j+1,m} \left( \frac{\rho_v}{z_k - z_v} \right)^{m+1} (2A_{v,m+l+1})$$

for $j = 0, 1, \ldots, M - 1$, then

$$\begin{bmatrix} a_{0,v}^k \\ a_{1,v}^k \\ \vdots \\ a_{M-1,v}^k \end{bmatrix} = -P_{k,v}$$

$$\begin{bmatrix} 2A_{v,M+l} \\ 2A_{v,M+l-1} \\ \vdots \\ 2A_{v,l+1} \end{bmatrix}.$$
We have already seen how to compute the matrices $P_{k,v}$. As to $h_k(z_k + \rho_k e^{-i\theta})$, it is clear from (30) that it can be evaluated by the FFT.

8. Numerical examples

We now compare both methods on some numerical examples.

Example 1. We use the exact map $f$ from [7], Section 6, modified to satisfy our normalization. $f$ maps the exterior of two circles with centers 0, $(x_1 + x_2)/2$ and radii 1, $(x_1 - x_2)/2$ onto an unbounded doubly connected region. The map is a composition of elementary maps,

$$f(z) = f_5(f_4(f_3(f_2(f_1(z))))).$$

The first map $f_1$ is the fractional linear map

$$f_1(z) = \frac{z-a}{az-1},$$

where

$$a = \frac{x_1x_2 + \sqrt{(x_1^2 - 1)(x_2^2 - 1)}}{x_1 + x_2}, \quad R = \frac{x_1x_2 - 1 - \sqrt{(x_1^2 - 1)(x_2^2 - 1)}}{x_1 - x_2},$$

and $1 < x_2 < x_1$.

$$f_2(z) = \beta z, \quad f_3(z) = z + 1/z, \quad f_4(z) = \frac{\beta}{\beta^2 + 1},$$

where $\beta R \gg 1$ so that the region is not too extreme. The final map $f_5$ is the fractional linear map

$$f_5(z) = (C_1z + C_2)/(z + C_3),$$

where

$$C_1 = \frac{a^4 - \beta^2}{a(a^2 - \beta^2)}, \quad C_2 = -\frac{3a^2\beta^2 + a^2 - \beta^4 - 3\beta^2}{a^2\beta^2 + a^2 - \beta^2 - \beta^4}, \quad C_3 = \frac{a^2 + \beta^2}{a(\beta^2 + 1)}.$$

In this example we use $x_1 = 2, x_2 = 3, \beta = 30$. The tolerance for the residuals in the inner iteration is $1.0e - 15$. The initial guess for the boundary correspondence is given by $S_k(\theta) = \theta$. We let DF, DZ, and DR denote the maximum numerical errors for the boundary components, centers, and radii, respectively. From Tables 1 and 2, Wegmann’s and Fornberg’s methods attain similar discretization errors. The map is shown in Fig. 4.

Tables 3 and 4 give the numerical errors for a poorer initial guess, $z = [-0.1 + 0.1i; 2.6 + 0.2i]$, $r = [0.8; 0.4]$, for the centers and radii. Fornberg’s method is more sensitive to the initial guess than Wegmann’s method. Fig. 5 uses the same initial guess. Smoothing by zeroing half of the Fourier coefficients, as suggested in [28], is useful for both methods. Wegmann’s method exhibits convergence–divergence behavior in Fig. 5. Fornberg’s method may need more Newton iterations to achieve the same accuracy in this case.

#### Example 2.
A region of connectivity 5 bounded by arctanh, cassini oval, ellipse, inverted ellipse and sports ground curves. These boundaries are interpolated by periodic cubic splines parametrized by chordal arclength as described in [7]. In this example, we use $N = 128$. In Fig. 6, Fornberg’s method shows a better error decay than Wegmann’s method. The conformal map is displayed in Fig. 7.
9. Crowding for the circle map

The purpose of this section is to present some examples of the ill-conditioning, known as the crowding phenomenon, for conformal maps of multiply connected regions. A great deal of research has been done in the last 20 years on the crowding phenomenon, especially for the simply connected case; see [4] for references to some of the literature. Difficult cases for conformal mapping from exterior regions bounded by circles occur (i) when arcs of a circle map to the ends of elongated regions and (ii) when the circles are close to touching.
In this section, we are concerned with case (ii) when the circles are close to touching. This case also causes difficulty for the Koebe iteration [14,13,23] which uses simply connected maps to successively map the exterior of each boundary curve to the exterior of a circle. The numerical observations and linear convergence results, given in [14] for the Koebe map and in [29,7,1] for the inner linear systems in Newton-like methods, show that the convergence ratios for these methods are at most the inverse of the smallest magnification factor (greater than 1) which will cause two circles to touch. If any of the circles are already close to touching, this factor will be nearly 1 and the methods will converge very slowly. This situation also causes difficulties for computing solutions to related problems in potential flow and electrostatics, for instance, by the method of images [13], and requires special techniques [3].

We emphasize that the positions of the circles, though predetermined by the geometry, are not known in advance and must be computed. Multiply connected geometries which map to close-to-touching circles were noted by Halsey [13]. In particular, Halsey, [13], Fig. 5, gives an example of a map from the exterior of three thin ellipses with parallel major axes to the exterior of three nearly touching circles. In what follows we give two examples for which the maps and the associated measures of crowding are known explicitly, and compare our “exact” results with those computed by using our numerical method. Our two examples involve the mapping from two circles to two parallel and two collinear slits, respectively. In both of these cases, the crowding is due to elongated or narrow sections in the regions between the slits. In addition, we will compare the calculations for the slit regions to regions exterior to parallel and collinear ellipses with minor-to-major axis ratios of .1. Similar computational results using the Koebe iteration and initial attempts to derive crowding estimates are given in [23].
Example 1. Parallel slits and ellipses. For both of our examples, we will need the fractional linear transformation from the exterior of two circles to an annulus; see Fig. 8. Consider the region exterior to two circles with radii 1 and centers \( \pm i(1 + r) \) in the plane. This region can be mapped explicitly, to an annulus of inverse modulus \( R \approx 1 - \sqrt{8r} \) for small \( r \); see e.g., [12, p. 1279]. For small \( r \) the image of the axe-shaped region bounded by the circles and the dotted lines in Fig. 8 will nearly cover the entire annulus. The annulus can be mapped periodically by log to a rectangle of aspect ratio \( -\log R/2 \approx \sqrt{8r}/2 \) with the image of the origin mapped to the center of the rectangle.

The map from the region exterior to the parallel slits \([-1 + id, 1 + id], [-1 - id, 1 - id]\) in Fig. 8 to an annulus is given in [17, Section 13.12] in terms of elliptic functions. For a small distance \( d \) the image of the rectangle between the slits will almost fill the entire annulus. Equating the inverse moduli of these two annuli, we find \( 1 - \sqrt{8r} \approx 1 - 2\pi d \).

This gives the exact asymptotic crowding formula

\[
r \sim \frac{\pi^2 d^2}{2}, \quad r, d \to 0.
\]  

(31)

The more elongated (or narrower) the channel between the slits, the closer the circles will be. (Note that the behavior is not exponential in the aspect ratio \( d \) of the channel as one might expect from elongated simply connected maps [4].)

A comparison of these estimates \( r_{\text{est}} \) with the value of \( r_{\text{slit}} \) computed using our new numerical conformal mapping method is given in Table 5. The circles are normalized to have radii equal to 1. Generally, the method requires smooth boundaries. However, the method gives good overall results for maps to exteriors of slits, even though a close inspection of the tips of the slits reveal inaccuracies. The map uses \( N = 128 \) Fourier points on each disk. Results for parallel ellipses \( r_{\text{ell}} \) with centers separated by \( 2d \) are also listed in Table 5. The errors \( \text{error}_{\text{ell}} \) are the maximum pointwise errors in the boundary correspondences for the ellipses for \( N = 128 \) compared with the solution for \( N = 256 \). The errors in the centers and radii are usually \( 10^{-7} \sim 10^{-9} \). The change in the errors with \( d \) is not very severe or consistent, indicating that this form of crowding is not as great a problem as the case of elongated, simply connected regions. Figs. 9–11 display mappings of equally spaced Cartesian grid points in the circle domain in order to illustrate the distortions in the conformal maps.
Example 2. Collinear slits and ellipses. Here we consider the region exterior of two collinear slits $[-2 - d, -d], [d, 2 + d]$ in Fig. 12. The exact map from an annulus of outer radius 1 and inner radius $R < 1$ to the exterior of two slits $[1, 1/k]$ and $[-1/k, -1]$ is given in [17, Section 13.11], by $w = \text{sn}((-2K/\log(R)) \log(z/\sqrt{R}))$. Multiplication by $d = 2k/(1 - k)$ maps to our region exterior to slits $[d, 2 + d]$ and $[-2 - d, -d]$. From the properties of sn, we have that $K \sim \pi/2$ and $K' \sim \log(4/k) \approx \log(8/d)$ as $d \to 0$; see, e.g. [4, Section 3(i), p. 801]. Using the map from the exterior disks to the annulus gives $2\pi/\sqrt{8r} \sim -2\pi/\log R \sim K'/K$ and finally

$$r \sim \frac{\pi^4}{8(\log(d/8))^2} \quad \text{or} \quad d \sim 8e^{-\pi^2/\sqrt{8r}}$$

as $d \to 0$. Note that the crowding in this case is exponential in $-1/\sqrt{r}$.

Table 6

A comparison of this estimate with the value of $r$ computed using our new Fornberg-like map is given in Table 6. The results are compared to collinear ellipses of minor-to-major axis ratio .1 and length 2 with tips separated by $2d$. The errors are computed in the same way as the previous example with similar results. Mappings of equally spaced grid points are given in Figs. 13–15.
